Measuring the tax gap of business taxpayers in Australia

Abstract
The ‘tax gap’ is the difference between the tax that would have been determined if all taxpayers had reported all of their activities and transactions correctly, and the tax determined in practice. Generally, tax gap estimates exclude illegal sources of income. This article considers how best to estimate the tax gap attributable to business taxpayers in Australia.

tax gap, ATO, business taxpayers, tax collection
MEASURING THE TAX GAP OF BUSINESS TAXPAYERS IN
AUSTRALIA

SYLVIA VILLIOS*

The ‘tax gap’ is the difference between the tax that would have been
determined if all taxpayers had reported all of their activities and transactions
correctly, and the tax determined in practice. Generally, tax gap estimates
exclude illegal sources of income. This article considers how best to estimate
the tax gap attributable to business taxpayers in Australia.

In Australia, the government does not attempt to estimate the total tax gap but
instead undertakes vigorous risk assessments to identify and address areas where
this gap may be or potentially become significant. ¹ For example, in relation to the
Goods and Services Tax (GST) gap risk, the Australian Taxation Office (ATO)
develops indicators using Australian Bureau of Statistics (ABS) data, including GST
growth in relation to ABS household expenditure data, GST growth by surveys of
enterprise, GST trends by industry and indicators of ATO efficacy in relation to GST
fraud.²

This approach has been criticised by the Australian National Audit Office and the
Joint Committee of Public Accountants and Audit (JCPAA). In particular, JCPAA
have commented that the ATO should establish and maintain a dynamic mechanism
to determine an estimate of the tax gap using appropriate ABS economy-wide
business indicators.³

Tax gap estimation is beneficial and important as it is a means of identifying the
types and level of non-compliance that contribute to the tax gap. It can provide
improved efficiency of resource allocation within a revenue authority to combat non-
compliance and can also act as a measure of effectiveness of a revenue authority.

³  Ibid [71].
BACKGROUND

A tax gap may arise either because of assessment risk or collection risk. Assessment risk is the difference between tax that is due and tax actually assessed by the tax authorities as owing by the taxpayer. This includes the gap attributable to taxpayers underreporting their income and not lodging their tax returns. The major portion of the tax gap is caused by assessment risk (around 90% of the overall tax gap in developed economies).4

Collection risk is the difference between tax payments received and tax actually assessed by the taxpayer. In the US, this difference is largely caused by accidental non-compliance and employers’ failure to withhold income and employment taxes.5

METHODS OF TAX GAP ESTIMATION

Attempts to quantify the tax gap can be divided into macro and micro methods. Macro methods rely on macro indicator variables like monetary and physical input demand, or on information from national and financial accounts, to determine the overall size of the tax gap.

Conversely, micro methods rely on data retrieved from individual taxpayers in the form of surveys and tax audits. Such methods use a bottom-up approach to derive estimates of the size of the tax gap in the economy as a whole.

Macro Approaches to Tax Gap Estimation

The Currency Demand Methods

The currency demand method is based on the concept that dishonest taxpayers largely transact in cash in order to avoid leaving detectable traces. This model suggests the degree to which activities are shifted into the unofficial sector could be determined by the level of taxation, the complexity of the tax system, GDP per capita and the interest rate on savings deposits. Accordingly, this model is based on calculating the ‘excess’ demand for currency to estimate the size of the tax gap and explaining this by reference to these indicators.6

---

5  Ibid.
Physical Input Methods

The physical input method is based on the premise that electric power consumption is an appropriate indicator for overall economic activity. For example, electricity consumption has been used (as a proxy for the overall economy) minus estimated official GDP to estimate the tax gap.7

Macro Accounting Methods

Macro accounting approaches identify tax gaps by comparing data from national and financial accounts of countries. The underlying concept is that discrepancies in these accounts can be reconciled to estimate a country’s tax gap.

Micro Approaches to Tax Gap Estimation

Survey Methods

In developed economies, tax authorities also rely on survey methods to determine the size of the tax gap. A questionnaire survey can be in the form of telephone interviews, face-to-face interviews or postal questionnaires. For example, the Swedish tax authority sends out questionnaires to corporations and individuals regarding their activities and transactions, and undertakes surveys of particular sectors and occurrences.8

Tax Audit Methods

Tax audit methods involve observing persons and firms through careful audits of information supplied by taxpayers to the tax authorities. Audits about taxpayers’ own information regarding income and deductions can to some extent reveal the accuracy of such information. Provided the sampling process is random, it is straightforward to extrapolate the information retrieved in the tax audits to the whole taxpayer population.9

8 Swedish National Tax Agency, Tax Gap Map for Sweden – How was it created and how can it be used? (2008) <http://www.skatteverket.se/download/18.5c768f0c80005186/Report_2008_1B.pdf> at 1 February 2011.
One example of the use of the tax audit method is the National Research Program (NRP) conducted in the US in 2001, where the US government established a program to measure taxpayer compliance. NRP is based on a large sample of 46,000 tax returns that were randomly selected for review and examination. Using sample weights according to taxpayer characteristics, the information gained from the audits, and the non-compliance behaviour of the randomly selected taxpayer, a sample was extrapolated to the rest of the population and aggregated to measure the tax gap.

**Best Method to Use**

Each of the methods described above has various strengths and inherent weaknesses. Currency demand methods have been heavily criticised by the Organisation for Economic Co-operation and Development (OECD) that has commented such models are ‘unsuitable for estimating the underground economy primarily because they are based on modelling assumptions that cannot be justified…’. The Physical Input method has been criticised, as not all shadow economy activities require a considerable amount of electricity. Technical progress has made electricity more efficient, rendering tax gap estimates inaccurate.

Macro accounting methods can also produce inaccurate results given they are calculated based on national data that may be inaccurate for statistical reasons or insufficient data quality. Importantly, all of the macro methods discussed above have the disadvantage that they produce aggregate information on the tax gap only. A major advantage of micro methods is that the tax gap can be separated according to taxpayer groups and type of income tax being evaded. Accordingly, a study that measures the tax gap attributable to Australian business taxpayers should preferably adopt a micro method of measurement, either by survey or audit.

The disadvantages of survey methods are that they are costly and time consuming. Further, the accuracy of the data is dependent upon the willingness of respondents to answer questions truthfully. More specifically, the sensitivity of the topics of tax avoidance and evasion casts doubt upon the respondents’ veracity. Studies show that

---

13 Above n 8.
the results of tax gap estimate surveys are perceived to be very sensitive to the way
the questionnaire is formulated.14

Generally, micro approaches based on information from random tax audits are most
likely to deliver reliable tax gap estimates.15 However, in the small business context,
where cash transactions are commonplace, opportunities for evasion are high and
resources are often scarce for field auditing.16 Even when high investments are made
in auditing, uncovering ‘hidden cash’ is never an easy task without an adequate
audit trail.17 Given the small business sector comprises a large portion of the overall
Australian business population, audit methods are unlikely to be useful. Accordingly,
it appears a survey method is the better method to use for such research. This is especially so if the questionnaire is formulated so that it does not
suffer from problems related to subjectivity in the answers.

If a survey method is adopted to measure the tax gap attributable to Australian
business taxpayers, the next steps will involve considering sample selection and then
developing a survey instrument.

SURVEY METHOD

Sample Selection

The population of interest is Australian business taxpayers. The sampling frame for
this survey should come from the ABS business register. Using the ABS register
means the accuracy of the study will be reliant on the register being reliable and
comprehensive. This may be problematic in the event that there are high turnover
rates of businesses or if businesses deliberately fail to register totally or in part.

The ABS categorises Australian businesses by employment size ranges, industry,
main state of operation, institutional sector, type of legal structure and annual
turnover size ranges. For the purpose of this study, the best estimation of the tax gap

2011; M Dornstein, ‘Compliance with legal and bureaucratic rules: The case of self-
employed taxpayers in Israel’ (1976) 29 Human Relations 1019-1034.
can be made if Australian businesses are categorised by size. This is the most appropriate category as 96% of businesses in the Australian private sector are ‘small businesses’ (0 - 20 employees),\(^\text{18}\) and small business taxpayers perceive the tax system differently to other business taxpayers.\(^\text{19}\)

For the tax gap estimation to be as accurate as possible, all categories of business taxpayers (small, medium and large businesses) should be included in the sample. The sample selection should be representative of each category as a proportion of all categories of Australian business taxpayers. Therefore, the most appropriate sample selection method is the probability proportional to size (PPS) sampling method. This method will give more highly represented categories on the register a greater chance of selection than less represented ones. Specifically, the probability of selecting the category will be directly proportional to its size. For example, in this study, 96% of the sample selected will be small business taxpayers. In order to select a PPS sample, each category of business in the framework must have an associated ‘measure of size’ which is usually based on the total population. There were 2,132,412 actively trading businesses in Australia as at June 2011.\(^\text{20}\) This is the size measure that will provide the basis for selecting some categories of business with greater probability than others.

Once selection ranges are determined for the categories, a sample can be selected through a simple random selection so the information retrieved in the survey can be extrapolated to the entire Australian business taxpayer population. Given the large number of Australian businesses in each category on the register, it is unlikely the same business will be selected more than once, therefore rendering systematic selection unnecessary.\(^\text{21}\)

The Survey Instrument

Numerous statistical models have been developed to estimate ‘tax gap’. Much of the research in developing these statistical models has been to identify risk areas that are the sources of tax gap.22

The detailed knowledge the tax administrator usually generates regarding risk areas is essentially the source of the tax gap.

In developing the survey, the various risk areas regarding Australian business taxpayers have been considered, based on both Australian and international experiences.23 It is intended that an advanced statistical model can be then be applied to the survey responses, to extrapolate an estimate of the tax gap for business taxpayers in Australia.24

Section A considers the business taxpayers’ perception of government institutions and the ATO. Question 1 has been formulated around the proposition that firms operate in the underground economy (and consequently add to the tax gap) due to weaknesses in political and social institutions, like bureaucracy, over-regulation, corruption and a weak legal system.25

Question 2 is based on two Australian studies that have explored small business taxpayers’ perceptions of the tax office and the tax system.26 The willingness of small business taxpayers to establish a cooperative relationship with the ATO has not always been reciprocated in the past.27 Complaints of tax office inaccessibility have been widespread.28 Further studies report small business taxpayers as envisaging an

23 See Appendix 1.

24 See above n 21.

27 Ibid.

28 Ibid.
adversarial relationship with tax authorities and wanting to ‘win’ against ‘the taxman’.29

Section B considers the business taxpayer’s tax morale, that is, their intrinsic willingness to pay taxes. Studies indicate a relationship between low tax morale on the size of the shadow economy,30 suggesting the tax morale variable can explain up to one-third of the variation in the shadow economy.

A further study identifies five characteristics that increase a taxpayer’s morale including political inclusion, accountability and transparency, perceived fairness, effectiveness and the political commitment to shared prosperity.31 Question 3 is based on each of the five characteristics referred to in the study above.

Section C considers a business taxpayer’s attitude towards Australia’s economic growth. This section is based on studies which show that for a given tax system, economic growth results in higher tax revenues. This revenue finances a more capable public administration and better public goods, and may give rise to a cycle of development and state building.32 There are a number of determinants of economic growth that have been identified in the literature, including population growth, the average nutrition of the population, credible protection of property rights and democratic institutions.33 Question 4 considers the business taxpayer’s attitude toward each of the determinants of economic growth, with the exception of Australia’s democracy and democratic institutions measured in Section A.

Section D considers the business taxpayer’s tendency to act dishonestly. Questions 5, 6 and 7 are based upon a study which found that a lack of morals in a taxpayer is a significant cause of the shadow economy.34

Section E considers a business taxpayer’s attitude toward ATO efficiency. Studies show the size of a country’s tax gap depends on the scope and efficiency of the national tax administration. Generally, studies for developed economies have shown

32 Ibid.
33 Ibid.
a positive relationship between tax auditing effort and taxpayer compliance. Further, the risk of detection likely also plays a part in the extent of the shadow economy or tax evasion. Questions 10 and 11 consider Australian business taxpayers’ attitudes toward ATO presence. They also consider whether these taxpayers are concerned about the likelihood of being caught for tax evasion and the consequences.

Section F considers the behaviour of Australian business taxpayers that transact in cash. Studies indicate that by far the most important determinant of tax compliance is income source and that individuals fail to declare business income received in cash, at a rate of approximately 50%. The strong relationship between tax evasion and income source suggests the primary causal factor of evasion is opportunity.

Questions 10 and 11 gauge how much of the business taxpayer’s total revenue is collected in cash, both as a percentage and dollar value. Question 12 considers how much of the business taxpayer’s total business income was declared to the ATO. Question 13 further considers how much opportunity the business taxpayer has to illegally reduce their tax liability through cash transactions, whereas Question 14 investigates the business taxpayer’s opinion as to which types of business taxpayers have the best opportunity to reduce tax illegally through cash transactions. In this context business taxpayers are divided into the ABS statistical categories that have been modified in the sample selection process.

Section G examines the business taxpayer’s knowledge of tax law. In the Australian context, studies have found that small business taxpayers do not have adequate knowledge of tax law to meet their obligations.

In Australia, a high proportion of taxpayers (75%), including wage and salary earners, rely on a tax adviser or tax agent to complete their yearly tax returns. In most cases, the reason given for seeking such assistance is to fulfil tax obligations.
honestly and without fuss. Questions 14 and 15 concern how much information a taxpayer receives, from which sources, and the quality of that information. Question 16 considers whether in the taxpayer’s opinion, they have enough knowledge to comply with their tax obligations. Questions 17 and 18 consider whether the taxpayer relies on a tax advisor in preparing their tax return and their reason for doing so.

Section H considers the Australian business taxpayer’s attitude towards other determinants of the tax gap including, high tax burden, high costs of compliance, size of penalty and behaviour of peers.

This question is based on studies that demonstrate increases in the effective tax rate enhance a firm’s incentive to operate in the underground economy. It is not a significant part of the survey as there are other studies that fail to establish a significant and negative effect of taxes on the size of the shadow economy.

Further, industry groups and researchers point to the high costs of compliance for small business taxpayers as a reason why concealing income and over-stating deductions is generally accepted as being greater among small business owners.

Tax evasion and shadow market activities are also affected by the size of fines. A substantial body of research shows that taxpayers who believe their peers evade tax are more likely to evade tax themselves.

Section I concerns the business taxpayer’s business and personal demographics and Question 21 determines the category of business taxpayer. This may become

important if the study goes further to quantify the tax gap attributable to each category of business taxpayer.

Question 22 ascertains the gender, age, education level, income level and income source of the survey participant. This question is based on behavioural compliance literature which indicates that these factors may affect tax compliance.46

CONCLUSION

Currently, the Australian government undertakes rigorous risk assessments to identify and address areas where the tax gap may be significant or have the potential to become significant.47 It appears the next step is to use that information, coupled with further research, to measure Australia’s tax gap. Further, this research can be focused on various sectors and groups in the Australian economy. For example, this paper has considered a methodology that could be implemented to measure the tax gap attributable to Australian business taxpayers. By using such information, advancements can be made and ultimately, utilised to further enhance integrity in the Australian tax system.

APPENDIX 1

Australian Business Taxpayers – Tax Gap Study

Scope of the Survey

The tax gap is the difference between the tax that would have been determined if all taxpayers had reported all of their activities and transactions correctly, and the tax determined in practice.

AS AN AUSTRALIAN BUSINESS TAXPAYER, YOU HAVE BEEN CHOSEN AT RANDOM TO TAKE PART IN THIS SURVEY. If you are not an Australian business taxpayer, please return the blank survey form to Atax in the reply paid envelope provided.

Confidentiality

All responses received will be treated as strictly confidential and the ATO will not have access to individual replies. Please note that all responses are anonymous. In any case, the confidentiality of your reply will be preserved with only statistical summaries of the survey data being made available to the ATO.

Completing the Questionnaire

You can answer most questions by ticking the appropriate boxes provided. You will be able to answer all the questions without needing to consult your tax adviser. Answering the survey should take about 15 to 20 minutes. Please return your completed survey form to Atax in the reply paid envelopes provided.

Responses to this survey are confidential. Please do not include your name on this survey.

SECTION A PERCEPTION OF OUR INSTITUTIONS OF GOVERNMENT AND THE ATO

Qu 1. The following statements are possible opinions about Australian’s democracy. Please indicate how much you agree or disagree with each statement.
